AVL Analysis Interface Module (AIM) User Guide

June 12, 2017

Contents

1 Introduction

1.1 AVL AIM Overview

The use of lower-dimensional design tools is clearly desirable in a multidisciplinary/multi-fidelity aero design optimization setting. This is the crux of the Computational Aircraft Prototype Syntheses (CAPS) program. In many ways describing geometry appropriate for AVL (the Athena Vortex Lattice) code is more cumbersome than higher fidelity codes that require an Outer Mold Line. The goal is to make a CAPS AIM (Analysis Input Module) that directly feeds input to AVL and extracts the output quantities of interest from AVL's execution. This needs to be consistent with a build description that is hierarchical and multi-fidelity. That is, the build description that generates the geometric data at this level can be further enhanced to produce the complete OML of the aircraft design under consideration. As for the geometric description, AVL requires airfoil section data specified at the appropriate locations that describe the *skeleton* of the aircraft. These sections when *lofted* as groups and finally *unioned* together builds the OML. Clearly, intercepting the state of the geometry before these higher-level operations are applied provides the data appropriate for AVL. This naturally constructs a hierarchical geometric view where a design can progress into higher fidelities and feedback can be achieved where we can go back to this level of description when need be.

An outline of the AIM's inputs and outputs are provided in AIM Inputs and AIM Outputs, respectively.

The accepted and expected geometric representation and analysis intentions are detailed in Geometry Representation and Analysis Intent. Similarly other geometric attribution that the AIM makes use is provided in AIM attributes.

Upon running preAnalysis the AIM generates a two files, 1) "avlInput.txt" which contains the input information and control sequence for AVL to execute and 2) "caps.avl" which contains the the geometry to be analyzed. To populate output data the AIM expects a file, "avlOutput.txt", to exist after running AVL (see AIM Outputs for additional

information). An example execution for FLOPs looks like:

```
avl caps < avlInput.txt > avlOutput.txt"
```

1.2 Assumptions

The AVL coordinate system assumption (X – downstream, Y – out the right wing, Z – up) needs to be followed.

Within **OpenCSM** there are a number of airfoil generation UDPs (User Defined Primitives). These include NACA 4 series, a more general NACA 4/5/6 series generator, Sobieczky's PARSEC parameterization and Kulfan's CST parameterization. All of these UDPs generate **EGADS** *FaceBodies* where the *Face*'s underlying *Surface* is planar and the bounds of the *Face* is a closed set of *Edges* whose underlying *Curves* contain the airfoil shape. In all cases there is a *Node* that represents the *Leading Edge* point and one or two *Nodes* at the *Trailing Edge* – one if the representation is for a sharp TE and the other if the definition is open or blunt. If there are 2 *Nodes* at the back, then there are 3 *Edges* all together and closed, even though the airfoil definition was left open at the TE. All of this information will be used to automatically fill in the AVL geometry description.

The AVL Sections are automatically generated, one from each *FaceBody* and the details extracted from the geometry. **Xle**, **Yle**, and **Zle**, are taken from the *Node* Associated with the *Leading Edge*. The **Chord** is computed by getting the distance between the LE and TE (if there are 3 *Edges* in the *FaceBody* the TE point is considered the mid-position on that third *Edge*). **Ainc** is computed by registering the chordal direction of the *FaceBody* against the X-Z plane. The airfoil shapes are generated by sampling the *Curves* and put directly in the input file via the **AIRFOIL** keyword after being normalized.

It should be noted that general construction in either **OpenCSM** or even **EGADS** will be supported as long as the topology described above is used. But care should be taken when constructing the airfoil shape so that a discontinuity (i.e., simply C^0) is not generated at the *Node* representing the *Leading Edge*. This can be done by splining the entire shape as one and then intersecting the single *Edge* to place the LE *Node*.

The rest of the information and options required to fill out the AVL geometry input file (**xxx.avl**) will be found in the attributes attached to the *FaceBody* itself. The conventions used will be described in the next section.

Also note that this first implementation is not intended to provide complete control over AVL. In particular, there is no mention above of the **BODY**, **DESIGN**, **CLAF**, or **CDCL** AVL keywords.

1.3 Examples

An example problem using the AVL AIM may be found at AIM Examples, which contains example ∗.csm input files and pyCAPS scripts designed to make use of the AVL AIM. These example scripts make extensive use of the AIM attributes, AIM Inputs, and AIM Outputs.

2 AIM Examples

This example contains a set of ∗.csm and pyCAPS (∗.py) inputs that uses the AVL AIM. A user should have knowledge on the generation of parametric geometry in Engineering Sketch Pad (ESP) before attempting to integrate with any AIM. Specifically this example makes use of Design Parameters, Set Parameters, User Defined Primitive (UDP) and attributes in ESP.

The follow code details the process in a ∗.csm file that generates three airfoil sections to create a wing. Note to execute in serveCSM a dictionary file must be included "serveCSM -dict $ESP_ROOT/include/fidelity.dict avlDoc↩ Example1.csm"

First step is to define the analysis fidelity that the geometry is intended support.

```
attribute capsIntent       LINEARAERO
```

Next we will define the design parameters to define the wing cross section and planform.

```
despmtr   thick     0.12      frac of local chord
despmtr   camber    0.04      frac of loacl chord
despmtr   area      10.0      Planform area of the full span wing
despmtr   aspect    6.00      Span^2/Area
despmtr   taper     0.60      TipChord/RootChord
despmtr   sweep     20.0      1/4 Chord Sweep
despmtr   washout  -5.00      deg (negative is down at tip)
despmtr   dihedral  4.00      deg
```

The design parameters will then be used to set parameters for use internally to create geometry.

```
set       span      sqrt(aspect*area)
set       croot     2*area/span/(1+taper)
set       ctip      croot*taper
set       dxtip     (croot-ctip)/4+span/2*tand(sweep)
set       dztip     span/2*tand(dihedral)
```

Finally the airfoils are created using the User Defined Primitive (UDP) naca. The inputs used for this example to the UDP are Thickness and Camber. Cross sections are in the X-Y plane and are rotated to the X-Z plane. Reference quantities must exist on any body, otherwise AVL defaults to 1.0 for Area, Span, Chord and 0.0 for X,Y,Z moment References

```
# left tip
udprim    naca      Thickness thick     Camber    camber
attribute capsGroup    $Wing
attribute capsReferenceArea  area
attribute capsReferenceSpan  span
attribute capsReferenceChord croot
attribute capsReferenceX     croot/4
scale     ctip
rotatex   90        0         0
rotatey   washout   0         ctip/4
translate dxtip    -span/2    dztip

# root
udprim    naca      Thickness thick     Camber    camber
attribute capsGroup    $Wing
rotatex   90        0         0
scale     croot

# right tip
udprim    naca      Thickness thick     Camber    camber
attribute capsGroup    $Wing
scale     ctip
rotatex   90        0         0
rotatey   washout   0         ctip/4
translate dxtip     span/2    dztip
```

An example pyCAPS script that uses the above csm file to run AVL is a follows.

First the pyCAPS and os module needs to be imported.

```
try:
    import pyCAPS
except:
    print ("Unable to import pyCAPS module")
    raise SystemError
try:
    import os
except:
    print ("Unable to import os module")
    raise SystemError
```

Note if your Python major version is less than 3 (i.e. Python 2.7).the following statement should also be included so that print statements work correctly.

```
from __future__ import print_function
```

Once the modules have been loaded the problem needs to be initiated.

```
myProblem = pyCAPS.capsProblem()
```

Next the ∗.csm file is loaded and design parameter is changed - area in the geometry. Any despmtr from the avl↩ Wing.csm file are available inside the pyCAPS script. They are: thick, camber, area, aspect, taper, sweep, washout, dihedral

```
myGeometry = myProblem.loadCAPS("./csmData/avlWing.csm")

myGeometry.setGeometryVal("area", 10.0)
```

The AVL AIM is then loaded with the capsIntent set to LINEARAERO (this is consistent with the fidelity specified above in the ∗.csm file.

```
myAnalysis = myProblem.loadAIM(aim = "avlAIM",
                               analysisDir = "AVLAnalysisTest",
                               capsIntent = "LINEARAERO")
```

After the AIM is loaded the Mach number and angle of attack are set, though all AIM Inputs are available.

```
myAnalysis.setAnalysisVal("Mach", 0.5)
myAnalysis.setAnalysisVal("Alpha", 1.0)
myAnalysis.setAnalysisVal("Beta", 0.0)

wing = {"groupName"  : "Wing", # Notice Wing is the value for the capsGroup attribute
        "numChord"   : 8,
        "spaceChord" : 1.0,
        "numSpan"    : 12,
        "spaceSpan"  : 1.0}

myAnalysis.setAnalysisVal("AVL_Surface", [("Wing", wing)])
```

Once all the inputs have been set, preAnalysis needs to be executed. During this operation all the necessary files to run AVL are generated and placed in the analysis working directory (analysisDir)

```
myAnalysis.aimPreAnalysis()
```

An OS system call is then made from Python to execute AVL.

```
print ("Running AVL")
currentDirectory = os.getcwd() # Get our current working directory
os.chdir(myAnalysis.analysisDir) # Move into test directory
os.system("avl caps < avlInput.txt > avlOutput.txt");
os.chdir(currentDirectory) # Move back to working directory
```

A call to aimPostanalysis is then made to check to see if AVL executed successfully and the expected files were generated.

```
myAnalysis.aimPostAnalysis()
```

Similar to the AIM inputs, after the execution of AVL and aimPostanalysis any of the AIM's output variables (AIM Outputs) are readily available; for example,

```
print ("Alpha  " + str(myAnalysis.getAnalysisOutVal("Alpha")))
print ("Beta   " + str(myAnalysis.getAnalysisOutVal("Beta")))
print ("Mach   " + str(myAnalysis.getAnalysisOutVal("Mach")))
print ("pb/2V  " + str(myAnalysis.getAnalysisOutVal("pb/2V")))
print ("qc/2V  " + str(myAnalysis.getAnalysisOutVal("qc/2V")))
print ("rb/2V  " + str(myAnalysis.getAnalysisOutVal("rb/2V")))
print ("p'b/2V " + str(myAnalysis.getAnalysisOutVal("p'b/2V")))
print ("r'b/2V " + str(myAnalysis.getAnalysisOutVal("r'b/2V")))
print ("CXtot  " + str(myAnalysis.getAnalysisOutVal("CXtot")))
print ("CYtot  " + str(myAnalysis.getAnalysisOutVal("CYtot")))
print ("CZtot  " + str(myAnalysis.getAnalysisOutVal("CZtot")))
print ("Cltot  " + str(myAnalysis.getAnalysisOutVal("Cltot")))
print ("Cmtot  " + str(myAnalysis.getAnalysisOutVal("Cmtot")))
print ("Cntot  " + str(myAnalysis.getAnalysisOutVal("Cntot")))
print ("Cl'tot " + str(myAnalysis.getAnalysisOutVal("Cl'tot")))
print ("Cn'tot " + str(myAnalysis.getAnalysisOutVal("Cn'tot")))
print ("CLtot  " + str(myAnalysis.getAnalysisOutVal("CLtot")))
print ("CDtot  " + str(myAnalysis.getAnalysisOutVal("CDtot")))
print ("CDvis  " + str(myAnalysis.getAnalysisOutVal("CDvis")))
print ("CLff   " + str(myAnalysis.getAnalysisOutVal("CLff")))
print ("CYff   " + str(myAnalysis.getAnalysisOutVal("CYff")))
print ("CDind  " + str(myAnalysis.getAnalysisOutVal("CDind")))
print ("CDff   " + str(myAnalysis.getAnalysisOutVal("CDff")))
print ("e      " + str(myAnalysis.getAnalysisOutVal("e")))
```

results in

```
Alpha  1.0
Beta   0.0
Mach   0.5
pb/2V  -0.0
qc/2V  0.0
rb/2V  -0.0
p'b/2V 0.0
r'b/2V 0.0
CXtot  -0.00033
CYtot  1e-05
CZtot  -0.30042
Cltot  -0.0
Cmtot  -0.1947
Cntot  -1e-05
Cl'tot 0.0
Cn'tot 0.0
CLtot  0.30037
CDtot  0.00557
CDvis  0.0
CLff   0.29995
CYff   0.0
CDind  0.00557
CDff   0.00492
e      0.9692
```

The avlAIM supports the control surface modeling functionality inside AVL. Trailing edge control surfaces can be added to the above example by making use of the vlmControlName attribute. To add a **RightFlap** and **LeftFlap** to the previous example ∗.csm file the naca UDP entries are augmented with the following attributes.

```
# left tip
udprim    naca      Thickness thick     Camber    camber
attribute vlmControl_LeftFlap 80 # Hinge line is at 80% of the chord
...

# root
udprim    naca      Thickness thick     Camber    camber
attribute vlmControl_LeftFlap 80 # Hinge line is at 80% of the chord
attribute vlmControl_RightFlap 80 # Hinge line is at 80% of the chord
...

# right tip
udprim    naca      Thickness thick     Camber    camber
attribute vlmControl_RightFlap 80 # Hinge line is at 80% of the chord
...
```

Notice how the root airfoil contains two attributes for both the left and right flaps.

In the pyCAPS script the AIM Inputs, **AVL_Control**, must be defined.

```
flap = {"controlGain"     : 0.5,
        "deflectionAngle" : 10.0}

 myAnalysis.setAnalysisVal("AVL_Control", [("LeftFlap", flap),
                                           ("RightFlap", flap)])
```

Notice how the information defined in the **flap** variable is assigned to the vlmControl**Name** portion of the attributes added to the ∗.csm file.

3 AIM attributes

The following list of attributes drives the AVL geometric definition. Each *FaceBody* which relates to AVL **Sections** will be marked up in an appropriate manner to drive the input file construction. Many attributes are required and those that are optional are marked so in the description:

- **capsIntent** This attribute is a CAPS requirement to indicate the analysis fidelity the geometry representation supports. Options are: ALL, LINEARAERO
- **capsReferenceArea** [Optional: Default 1.0] This attribute may exist on any *Body*. Its value will be used as the SREF entry in the AVL input.

- **capsReferenceChord** [Optional: Default 1.0] This attribute may exist on any *Body*. Its value will be used as the CREF entry in the AVL input.
- **capsReferenceSpan** [Optional: Default 1.0] This attribute may exist on any *Body*. Its value will be used as the BREF entry in the AVL input.
- **capsReferenceX** [Optional: Default 0.0] This attribute may exist on any *Body*. Its value will be used as the Xref entry in the AVL input.
- **capsReferenceY** [Optional: Default 0.0] This attribute may exist on any *Body*. Its value will be used as the Yref entry in the AVL input.
- **capsReferenceZ** [Optional: Default 0.0] This attribute may exist on any *Body*. Its value will be used as the Zref entry in the AVL input.
- **capsGroup** This string attribute labels the *FaceBody* as to which AVL Surface the section is assigned. This should be something like: *Main_Wing*, *Horizontal_Tail*, and etc. This informs the AVL AIM to collect all *FaceBodies* that match this attribute into a single AVL Surface.
- **vlmControlName** This string attribute attaches a control surface to the *FaceBody*. The hinge location is defined as the double value between 0 or 1.0 (trailing edge). The range as percentage from 0 to 100 will also work. The name of the control surface is the string information after vlmControl (or vlmControl_). For Example to define a control surface named Aileron the following are identical (*attribute vlmControlAileron 0.8* or *attribute vlmControl_Aileron 80*) . Multiple *vlmControl* attributes, with different names, can be defined on a single *FaceBody*.

4 Geometry Representation and Analysis Intent

The geometric representation for the AVL AIM requires that "body(ies)" [or cross-sections], be a face body(ies) (FACEBODY) with the attribute **capsIntent** being set to **LINEARAERO** (intents of ALL also accepted).

5 AIM Inputs

The following list outlines the AVL inputs along with their default value available through the AIM interface.

- **Mach = 0.0**
  Mach number.
- **Alpha = NULL**
  Angle of attack [degree]. Either CL or Alpha must be defined but not both.
- **Beta = 0.0**
  Sideslip angle [degree].
- **RollRate = 0.0**
  Non-dimensional roll rate.
- **PitchRate = 0.0**
  Non-dimensional pitch rate.
- **YawRate = 0.0**
  Non-dimensional yaw rate.
- **CDp = 0.0**
  A fixed value of profile drag to be added to all simulations.
- **AVL_Surface = NULL**
  See Vortex Lattice Surface for additional details.

- **AVL_Control = NULL**
  See Vortex Lattice Control Surface for additional details.
- **CL = NULL**
  Coefficient of Lift. AVL will solve for Angle of Attack. Either CL or Alpha must be defined but not both.

6 aimInputsFUN3D

- **Moment_Center = NULL, [0.0, 0.0, 0.0]**
  Array values correspond to the Xref, Yref, and Zref variables. Alternatively, the geometry (body) attributes "capsReferenceX", "capsReferenceY", and "capsReferenceZ" may be used to specify the X-, Y-, and Z-reference centers, respectively (note: values set through the AIM input will supersede the attribution values).

7 AIM Outputs

Optional outputs that echo the inputs. These are parsed from the resulting output and can be used as a sanity check.

- **Alpha =** Angle of attack.
- **Beta =** Sideslip angle.
- **Mach =** Mach number.
- **pb/2V =** Non-dimensional roll rate.
- **qc/2V =** Non-dimensional pitch rate.
- **rb/2V =** Non-dimensional yaw rate.
- **p'b/2V =** Non-dimensional roll acceleration.
- **r'b/2V =** Non-dimensional yaw acceleration.

Calculated outputs. See AVL documentation for a description of each quantity.

- **CXtot**
- **CYtot**
- **CZtot**
- **Cltot**
- **Cmtot**
- **Cntot**
- **Cl'tot**
- **Cn'tot**
- **CLtot**
- **CDtot**
- **CDvis**
- **CLff**
- **CYff**

- **CDind**
- **CDff**
- **e**

Stability-axis derivatives - Alpha:

- **CLa** = z' force, CL, with respect to alpha.
- **CYa** = y force, CY, with respect to alpha.
- **Cl'a** = x' moment, Cl', with respect to alpha.
- **Cma** = y moment, Cm, with respect to alpha.
- **Cn'a** = z' moment, Cn', with respect to alpha.

Stability-axis derivatives - Beta:

- **CLb** = z' force, CL, with respect to beta.
- **CYb** = y force, CY, with respect to beta.
- **Cl'b** = x' moment, Cl', with respect to beta.
- **Cmb** = y moment, Cm, with respect to beta.
- **Cn'b** = z' moment, Cn', with respect to beta.

Stability-axis derivatives - Roll rate, p':

- **CLp** = z' force, CL, with respect to roll rate, p'.
- **CYp** = y force, CY, with respect to roll rate, p'.
- **Cl'p** = x' moment, Cl', with respect to roll rate, p'.
- **Cmp** = y moment, Cm, with respect to roll rate, p'.
- **Cn'p** = z' moment, Cn', with respect to roll rate, p'.

Stability-axis derivatives - Pitch rate, q':

- **CLq** = z' force, CL, with respect to pitch rate, q'.
- **CYq** = y force, CY, with respect to pitch rate, q'.
- **Cl'q** = x' moment, Cl', with respect to pitch rate, q'.
- **Cmq** = y moment, Cm, with respect to pitch rate, q'.
- **Cn'q** = z' moment, Cn', with respect to pitch rate, q'.

Stability-axis derivatives - Yaw rate, r':

- **CLr** = z' force, CL, with respect to yaw rate, r'.
- **CYr** = y force, CY, with respect to yaw rate, r'.
- **Cl'r** = x' moment, Cl', with respect to yaw rate, r'.
- **Cmr** = y moment, Cm, with respect to yaw rate, r'.
- **Cn'r** = z' moment, Cn', with respect to yaw rate, r'.

Body-axis derivatives - Axial velocity, u:

- **CXu** = x force, CX, with respect to axial velocity, u.
- **CYu** = y force, CY, with respect to axial velocity, u.
- **CZu** = z force, CZ, with respect to axial velocity, u.
- **Clu** = x moment, Cl, with respect to axial velocity, u.
- **Cmu** = y moment, Cm, with respect to axial velocity, u.
- **Cnu** = z moment, Cn, with respect to axial velocity, u.

Body-axis derivatives - Sideslip velocity, v:

- **CXv** = x force, CX, with respect to sideslip velocity, v.
- **CYv** = y force, CY, with respect to sideslip velocity, v.
- **CZv** = z force, CZ, with respect to sideslip velocity, v.
- **Clv** = x moment, Cl, with respect to sideslip velocity, v.
- **Cmv** = y moment, Cm, with respect to sideslip velocity, v.
- **Cnv** = z moment, Cn, with respect to sideslip velocity, v.

Body-axis derivatives - Normal velocity, w:

- **CXw** = x force, CX, with respect to normal velocity, w.
- **CYw** = y force, CY, with respect to normal velocity, w.
- **CZw** = z force, CZ, with respect to normal velocity, w.
- **Clw** = x moment, Cl, with respect to normal velocity, w.
- **Cmw** = y moment, Cm, with respect to normal velocity, w.
- **Cnw** = z moment, Cn, with respect to normal velocity, w.

Body-axis derivatives - Roll rate, p:

- **CXp** = x force, CX, with respect to roll rate, p.
- **CYp** = y force, CY, with respect to roll rate, p.
- **CZp** = z force, CZ, with respect to roll rate, p.
- **Clp** = x moment, Cl, with respect to roll rate, p.
- **Cmp** = y moment, Cm, with respect to roll rate, p.
- **Cnp** = z moment, Cn, with respect to roll rate, p.

Body-axis derivatives - Pitch rate, q:

- **CXq** = x force, CX, with respect to pitch rate, q.
- **CYq** = y force, CY, with respect to pitch rate, q.
- **CZq** = z force, CZ, with respect to pitch rate, q.
- **Clq** = x moment, Cl, with respect to pitch rate, q.

- **Cmq** = y moment, Cm, with respect to pitch rate, q.
- **Cnq** = z moment, Cn, with respect to pitch rate, q.

Body-axis derivatives - Yaw rate, r:

- **CXr** = x force, CX, with respect to yaw rate, r.
- **CYr** = y force, CY, with respect to yaw rate, r.
- **CZr** = z force, CZ, with respect to yaw rate, r.
- **Clr** = x moment, Cl, with respect to yaw rate, r.
- **Cmr** = y moment, Cm, with respect to yaw rate, r.
- **Cnr** = z moment, Cn, with respect to yaw rate, r.

8 Vortex Lattice Surface

Structure for the Vortex Lattice Surface tuple = ("Name of Surface", "Value"). "Name of surface defines the name of the surface in which the data should be applied. The "Value" can either be a JSON String dictionary (see Section JSON String Dictionary) or a single string keyword string (see Section Single Value String).

8.1 JSON String Dictionary

If "Value" is a JSON string dictionary (eg. "Value" = {"numChord": 5, "spaceChord": 1.0, "numSpan": 10, "space↩ Span": 0.5}) the following keywords (= default values) may be used:

- **groupName = "(no default)"**
  Single or list of *capsGroup* names used to define the surface (e.g. "Name1" or ["Name1","Name2",...]. If no groupName variable is provided an attempted will be made to use the tuple name instead;

- **noKeyword = "(no default)"**
  "No" type. Options: NOWAKE, NOALBE, NOLOAD.

- **numChord = 10**
  The number of chordwise horseshoe vortices placed on the surface.

- **spaceChord = 0.0**
  The chordwise vortex spacing parameter.

- **numSpan = 10**
  The number of spanwise horseshoe vortices placed on the surface.

- **spaceSpan = 0.0**
  The spanwise vortex spacing parameter.

- **yMirror = False**
  Mirror surface about the y-direction.

8.2 Single Value String

If "Value" is a single string the following options maybe used:

- (NONE Currently)

9 Vortex Lattice Control Surface

Structure for the Vortex Lattice Control Surface tuple = ("Name of Control Surface", "Value"). "Name of control surface defines the name of the control surface in which the data should be applied. The "Value" must be a JSON String dictionary (see Section JSON String Dictionary).

9.1 JSON String Dictionary

If "Value" is a JSON string dictionary (eg. "Value" = {"deflectionAngle": 10.0}) the following keywords (= default values) may be used:

- **deflectionAngle = 0.0**
  Deflection angle of the control surface.

- **leOrTe = (no default)**
  Is the control surface a leading (= 0) or trailing ($>$ 0) edge effector? Overrides the assumed default value set by the geometry: If the percentage along the airfoil chord is $<$ 50% a leading edge flap is assumed, while $>=$ 50% indicates a trailing edge flap.

- **controlGain = 1.0**
  Control deflection gain, units: degrees deflection / control variable

- **hingeLine = [0.0 0.0 0.0]**
  Alternative vector giving hinge axis about which surface rotates

- **deflectionDup = 0**
  Sign of deflection for duplicated surface

9.2 Single Value String

If "Value" is a single string the following options maybe used:

- (NONE Currently)
